

First and foremost, by submitting your assignment you certify that **you are the only author(s) of both the modifications to the code given to you and the report you have produced**. If you decide to use work by others, you **must state it explicitly**; if it's a core part of your work discuss it with us to make sure we consider it acceptable. This will be checked (remember that claiming somebody else's work is yours is illegal), and you will be asked questions about your source code during the oral exam. If we find that you violated these provisions, the exam will fail and you will need to restart from scratch, with different extensions, and lose any progress with the written exam.

Using large language models (e.g., CoPilot, ChatGPT, etc.) is allowed, but you **must** state clearly and **in detail** how you used them (i.e., did you use them to brainstorm the modifications? To write code? How many lines? To review code? To perform bug fixes? To write the reports? How many parts and according to which process?).

With the source code you used for your simulations and evaluations, submit a report: a PDF document that documents what you have done and the results you obtained. It should be a document that answers these questions:

- What questions lead you to this simulator extension?
 - Why do you think they are relevant?
- How did you do that?
 - Try to be at the right level of detail: don't include obvious/boring details, and discuss anything that is not obvious.
 - Aim at a document that should be clear to somebody who knows both the original simulator and the programming language.
 - Describe any unexpected, surprising, and interesting things you found.
- What is the answer to the original questions you asked?
 - Why is that? What is your interpretation of the results you obtained?

Consider the questions that will be answered in the peer review phase, described in the following, when drafting your document. After the peer review phase, work on a final version which will take into account the comments you received and what you have learned while reviewing another group's submission. Don't include the previous version in the final report but update it in place, and **document the changes** stemming from the peer review process in a separate section.

While writing the peer review you send to your colleagues, you should consider (and answer, where it makes sense) these questions:

- What is the motivation for the extension? Is the question the writers are asking themselves relevant?
- Did you find mistakes in the code or report? If so, please explain clearly.
- Is the report reproducible (i.e., does it give enough info for a reader familiar with the programming language to reproduce the results without leaving out details that are not straightforward)?
- Does the code work? Does it allow, in a clear and easily understandable way, to reproduce the results described in the report?
- Do the experimental results answer the original questions?
- Could the results (e.g., tables, plots) be better presented to answer the original questions in a more precise or easier-to-read format?
- Is there irrelevant content, or content that could be moved to an appendix that is useful for completeness/reproducibility but not needed for an average reader?
- If you are using content from outside the course, are you properly referencing all of it and making clear what is not done by you?
- Could the report be written in an easier-to-read and/or more concise way while not losing value for the reader (take the answers to the above points as guidance)?

Peer review comments should strive to be clear and **actionable** -- i.e., readers should know how to improve their assignment from the comments.

Peer reviews will be evaluated based on their usefulness in improving the reviewed work.
